

Task: Fix 3 bugs with AI help

Bug #1 — Missing Input Validation on "Number of Days"

Symptom: If a user leaves "Number of Days" empty (or types something invalid), the app would send a broken prompt to Gemini instead of catching the problem upfront.

Diagnosis: No input validation existed on `days_entry` before building the prompt — the raw text was used directly without checking if it was a valid number between 1-7.

Fix: Added a validation check at the start of `generate_meal_plan_thread()` that verifies the input is a digit within range, showing a clear warning message instead of proceeding if not.

Bug #2 — App Hangs Indefinitely Without Threading

Symptom: After clicking "Generate Meal Plan," the app got stuck showing "Generating..." for several minutes with no meal plan ever appearing — the window itself remained draggable/closable, but the app never progressed or responded to the request.

Diagnosis: The Gemini API call was made directly on the main thread instead of a background thread. Without threading, there's no separate process handling the response — if the call takes unusually long or silently stalls, the app has no way to update the UI or recover, since everything is tied to that single blocked call.

Fix: Restored the background threading pattern — wrapping the API call in `threading.Thread(target=fetch_meal_plan)` and calling `.start()`, so the request runs independently and the app can properly receive and display the result once it completes.

Bug #3 — KeyError from a Typo in Dictionary Key

Symptom: Immediately after generating a meal plan, the app crashes with an unhandled exception the moment it tries to build the meal cards — no cards are ever displayed, and the app throws an error instead of showing the results page.

Diagnosis: In `create_meal_card()`, the code referenced `meal['nmae']` (a typo) instead of the correct key `meal['name']`. Since Python dictionaries require exact key names, accessing a key that doesn't exist raises a `KeyError`, and this crash happened inside a Tkinter callback triggered by `app.after()`, which meant it wasn't caught by any of the existing `try/except` blocks elsewhere in the app.

Fix: Corrected the typo, changing `meal['nmae']` back to `meal['name']`.
